GENERALIZED LOW-DENSITY PARITY CHECK CODES (GLDPC)

FIELD

The present disclosure relates to Generalized Low-Density Parity-Check (GLDPC) codes for channel coding in digital communication systems. In particular, the present disclosure relates to GLDPC codes which allow for easy encoding.

BACKGROUND

Fig. 1 shows a block diagram illustrating a generic digital communications system 10 in which the elements of the present disclosure may be implemented. The system 10 includes a transmitting side 10a comprising a generic encoder 12 and a receiving side 10b comprising a generic decoder 14. The input of the generic encoder 12 at the transmitting side may be an information sequence IS_1 of k bits to which a redundancy sequence of r bits is added in an encoding operation performed by the generic encoder 12, thereby producing an encoded information sequence IS_2 of $k+r=n$ bits which may be forwarded to a modulator 16.

The modulator 16 may transform the bit sequence IS_2 into a modulated signal vector CH_IN which is in turn transmitted through a channel 18 such as, for example, a radio channel or an optical channel. Since the channel 18 is usually subject to noisy disturbances, the channel output CH_OUT may differ from the channel input CH_IN.

At the receiving side 10b, the channel output vector CH_OUT may be processed by a demodulator 20 which produces reliability values (e.g., likelihoods, likelihood ratios, or log likelihood ratios) regarding the bit values of the received bit sequence IS_3 . The generic decoder 14 may use the redundancy in the received bit sequence IS_3 in a decoding operation to correct errors and produce a decoded information sequence IS_4 which is an estimate of the information sequence IS_1 .

The encoding operation and the decoding operation may be governed by an LDPC code that defines the redundancy sequence to be added to an information sequence IS_1 . In other words, an LDPC code provides a rule set to establish a codebook that contains all possible code words to be transmitted through the channel 18. This allows identifying and possibly correcting
 5 transmission errors which reveal themselves in received bit sequence IS_3 that does not correspond to a code word contained in the codebook established by the LDPC code on which the transmission is based.

In the general formulation of channel coding, an LDPC code may employ a generator matrix G for the encoding operation in the generic encoder 12 and a parity-check matrix H for the
 10 decoding operation in the generic decoder 14.

For a LDPC code with an information sequence IS_1 of size $1 \times k$, a code word IS_2 of size $1 \times n$ and a redundancy (parity) sequence of $r = (n - k)$ bits, the generator matrix G has size $k \cdot n$, and the parity-check matrix H has size $r \cdot n = (n - k) \cdot n$. The parity-check matrix H_{rxn} and the generator matrix G_{kxn} enjoy the orthogonality property, which states that for any generator
 15 matrix G_{kxn} with k linearly independent rows there exists a parity-check matrix H_{rxn} with $r = (n - k)$ linearly independent rows. Thus, any row of the generator matrix G_{kxn} is orthogonal to the rows of the parity-check matrix H_{rxn} such that the following equation is satisfied:

$$G_{kxn} \cdot H_{rxn}^T = 0$$

20 The encoding operation can be performed by means of a multiplication between the information sequence IS_1 and the generator matrix G_{kxn} , wherein the result of the multiplication provides the encoded output sequence IS_2 as follows:

$$IS_2 = IS_1 \cdot G_{kxn}$$

At the receiving side, due to the orthogonality property between the generator matrix G_{kxn} and the parity-check matrix H_{rxn} , the following equation should be satisfied:

$$H_{rxn} \cdot IS_3^T = 0$$

where IS_3 is the received information sequence of size $1xn$. If the above equation is verified,
5 the information signal estimate IS_4 is likely to be correct.

Once the parity-check matrix H_{rxn} is generated, it is possible to obtain the generator matrix G_{kxn} and vice versa. Accordingly, any process of determining a parity-check matrix H_{rxn} may be mapped to an equivalent process of obtaining a generator matrix G_{kxn} , so that any process disclosed throughout the description and claims in relation to determining a parity-check matrix
10 H_{rxn} shall be understood as encompassing the equivalent process of obtaining a generator matrix G_{kxn} and vice versa.

For employing an LDPC code in the generic encoder 12 and the generic decoder 14, the generic encoder 12 and the generic decoder 14 may be provided with data/parameters defining the generator matrix G_{kxn} and parity-check matrix H_{rxn} , respectively. The provided
15 data/parameters may be processed by one or more processors at the encoder 12 or the decoder 14, or the provided data/parameters may be “mapped” to customized hardware such as, for example, one or more application specific integrated circuits (ASICs) and/or one or more field programmable gate arrays (FPGAs), that perform the involved calculations. Moreover, an apparatus configured to determine the data/parameters may be integrated in (or connected to)
20 the generic encoder 12 and/or the generic decoder 14.

Moreover, a parity-check matrix H_{rxn} can be described by its equivalent bipartite graph (“Tanner graph”), wherein each edge of the Tanner graph connects one variable node of a plurality of variable nodes (which form the first set of the bipartite graph) to one check node of a plurality of check nodes (which form the second set of the bipartite graph). For example, a
25 parity-check matrix H_{rxn} of r rows and n columns can be represented by an equivalent bipartite

graph with r check nodes and n variable nodes which has edges between the check nodes and the variable nodes if there are corresponding “1s” in the parity-check matrix H_{rxn} (cf. R. Tanner, “*A Recursive Approach to Low Complexity Codes*”, IEEE TRANSACTIONS IN INFORMATION THEORY, Volume 27, Issue 5, Pages 533-547, September 1981). Thus, the
 5 variable nodes represent code word bits and the check nodes represent parity-check equations.

In the Tanner graph of an LDPC code, any degree- s check node may be interpreted as a length- s single parity-check code, i.e., as an $(s, s - 1)$ linear block code. Thus, for generalizing an LDPC code, check nodes of the LDPC code may be replaced with a linear block code to enhance the overall minimum distance between the code words (cf. M. Lentmaier et al., “*On Generalized*
 10 *Low-Density Parity-Check Codes based on Hamming Component Codes*”, IEEE COMMUNICATIONS LETTERS, Volume 3, Issue 8, Pages 248-250, August 1999).

While the above approaches to channel coding such as generalized LDPC block codes have proven to perform well for a wide variety of scenarios, the urge for higher data throughput requires even more sophisticated solutions that achieve high data throughput with decent
 15 encoding/decoding resources. It is thus the object of the present invention to provide for a more efficient forward error correction channel coding technique applicable to the generic digital communications system 10. In this regard, it is noted that some or all of the above-described features may form part of implementation forms of the present invention as described in the following

20 SUMMARY

According to a first aspect of the present invention, there is provided a system for determining a GLDPC code for forward error correction channel coding, the system being configured to determine $2k$ parity check matrix columns of size k , label components of a first parity check matrix with n columns and k rows, wherein the first parity check matrix includes the $2k$
 25 parity check matrix columns of size k , and select Cordaro-Wagner component code check matrices, wherein each of the selected Cordaro-Wagner component code check matrices has two rows which replace one row of the first parity check matrix to derive a second parity check matrix defining the generalized LDPC code, wherein the determining of the $2k$ parity check

matrix columns of size k and the selecting of the Cordaro-Wagner component code check matrices are constrained to $2k$ parity check matrix columns of size k and Cordaro-Wagner component code check matrices which allow that rows and columns of a parity part consisting of $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k , can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

In this regard, it is noted that the term “matrix” as used throughout the description and claims in particular refers to a set of (integer) values stored in a (logical) memory array or having assigned row and column indices. If not involving matrix algebra, or if respective matrix algebra routines are suitably redefined, the notion of rows and columns may even be changed or freely chosen. However, throughout the description and claims it is adhered to the mathematical concepts and notations regularly used in the art and they shall be understood as encompassing equivalent mathematical concepts and notations.

Thus, the structure of the parity part of the first parity check matrix (i.e., the columns of the first parity check matrix corresponding to the redundancy sequence) may be constrained such that the additional freedom in replacing rows of the first parity check matrix with rows of a Cordaro-Wagner component code check matrices can be exploited to achieve (optionally after a column permutation) a repeat-accumulate code structure (triangular form of the parity part of the second parity check matrix).

In a first possible implementation form of the system according to the first aspect, the system is configured to split/duplicate each entry of the $2k$ parity check matrix columns of size k into a vector of size two, wherein each vector of size two having a non-zero weight requires a corresponding non-zero entry, to determine the $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k , and can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

Hence, the columns of size k may be expanded by replacing each column entry with a vector of size two such that the parity part formed by the $2k$ columns of the second parity check matrix has a size of $2k \times 2k$ and a triangular form.

In a second possible implementation form of the system according to the first aspect, the system is configured to iteratively label components of $n - k$ unlabeled columns of the first parity check matrix based on a performance measure.

For example, columns of the information part may be iteratively labelled, wherein different labelling options may be compared and an option may be chosen if it leads to a higher girth of the code and/or a higher extrinsic message degree, EMD, or a higher approximated cycle EMD, ACE, of a smallest cycle generated by the option (as compared to other options). Thus, while the parity part may be labelled first and then kept substantially static to allow for easy encoding, the information part (i.e., the columns corresponding to the parity bits) may be labelled for best performance.

In a third possible implementation form of the system according to the first aspect, the system is configured to compare multiple alternatives for labelling different components of the $n - k$ columns with non-zero entries and select one alternative achieving a highest performance score.

Hence, labelling may correspond to iteratively adding edges in the Tanner graph representation, wherein, for example, a progressive edge growth algorithm may be used to label the information part of the first parity check matrix.

In a fourth possible implementation form of the system according to the first aspect, a column of the Cordaro-Wagner component code check matrix is to have zero weight if a corresponding component of the row of the first parity check matrix is zero.

In this regard, it is noted that the vectors of size two may correspond to the columns of the Cordaro-Wagner component code check matrices such that the first parity check matrix may define an interleaver structure for Cordaro-Wagner component code en-/decoding units that

correspond to super-check nodes, wherein each super-check node represents two check nodes of the Tanner graph representation of the second parity check matrix.

In a fifth possible implementation form of the system according to the first aspect, each of the $2k$ parity check matrix columns of size k has weight one or two.

- 5 In a sixth possible implementation form of the system according to the first aspect, $k - 1$ parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have a weight of one and the remaining parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have weight two.

- 10 In a seventh possible implementation form of the system according to the first aspect, the $2k$ parity check matrix columns of size k are linearly independent.

In an eighth possible implementation form of the system according to the first aspect, selecting the Cordaro-Wagner component code check matrices includes replacing each non-zero entry in a row of the first parity check matrix with a non-zero column of a Cordaro-Wagner component code check matrix, wherein:

- 15 • a row having exactly three non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix, where the columns of the Cordaro-Wagner component code check matrix which correspond to the $2k$ parity check matrix columns are linearly independent; and
- 20 • a row having exactly four non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix, where the columns Cordaro-Wagner component code check matrix which correspond to the $2k$ parity check matrix columns comprise three linearly independent columns.

- 25 The fifth to the eighth possible implementation forms facilitate achieving a repeat-accumulate code structure.

According to a second aspect of the present invention, there is provided a method of determining a GLDPC code for forward error correction channel coding, the method comprising determining $2k$ parity check matrix columns of size k , labeling components of a first parity check matrix with n columns and k rows, wherein the first parity check matrix includes the $2k$ parity check matrix columns of size k , and selecting Cordaro-Wagner component code check matrices, wherein each of the selected Cordaro-Wagner component code check matrices has two rows which replace a row of the first parity check matrix to derive a second parity check matrix defining the generalized LDPC code, wherein the determining of the $2k$ parity check matrix columns of size k and the selecting of the Cordaro-Wagner component code check matrices are constrained to $2k$ parity check matrix columns of size k and Cordaro-Wagner component code check matrices which allow that rows and columns of a parity part consisting of $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

As indicated above, this constrains the structure of the parity part of the first parity check matrix (i.e., the columns of the first parity check matrix corresponding to the redundancy sequence) such that the additional freedom in replacing rows of the first parity check matrix with rows of a Cordaro-Wagner component code check matrices can be exploited to achieve (optionally after a column permutation) a repeat-accumulate code structure (triangular form of the parity part of the second parity check matrix).

In a first possible implementation form of the method according to the second aspect, the method comprises splitting/duplicating each entry of the $2k$ parity check matrix columns of size k into a vector of size two, wherein each vector of size two having a non-zero weight requires a corresponding non-zero entry, to determine the $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k , and can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure

Hence, as indicated above, the columns of size k may be expanded by replacing each column entry with a vector of size two such that the parity part formed by the $2k$ columns of the second parity check matrix has a size of $2k \times 2k$ and a triangular form.

In a second possible implementation form of the method according to the second aspect, the method comprises iteratively labeling components of $n - k$ unlabeled columns of the first parity check matrix based on a performance measure.

For example, as indicated above, columns of the information part may be iteratively labelled, wherein different labelling options may be compared and an option may be chosen if it leads to a higher girth of the code and/or a higher extrinsic message degree, EMD, or a higher approximated cycle EMD, ACE, of a smallest cycle generated by the option (as compared to other options). Thus, while the parity part may be labelled first and then kept substantially static to allow for easy encoding, the information part (i.e., the columns corresponding to the parity bits) may be labelled for best performance.

In a third possible implementation form of the method according to the second aspect, the method comprises comparing multiple alternatives for labelling different components of the $n - k$ columns with non-zero entries and selecting one alternative achieving a highest performance score.

Hence, as indicated above, labelling may correspond to iteratively adding edges in the Tanner graph representation, wherein, for example, a progressive edge growth algorithm may be used to label the information part of the first parity check matrix.

In a fourth possible implementation form of the method according to the second aspect, a column of the Cordaro-Wagner component code check matrix has zero weight if a corresponding component of the row of the first parity check matrix is zero.

As indicated above, the vectors of size two may correspond to the columns of the Cordaro-Wagner component code check matrices such that the first parity check matrix may define an interleaver structure for Cordaro-Wagner component code en-/decoding units that correspond to super-check nodes, wherein each super-check node represents two check nodes of the Tanner graph representation of the second parity check matrix.

In a fifth possible implementation form of the method according to the second aspect, each of the $2k$ parity check matrix columns of size k has weight one or two.

In a sixth possible implementation form of the method according to the second aspect, $k - 1$ parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have a weight of one and the remaining parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have weight two.

In a seventh possible implementation form of the method according to the second aspect, the $2k$ parity check matrix columns of size k are linearly independent.

In an eighth possible implementation form of the method according to the second aspect, selecting the Cordaro-Wagner component code check matrices includes replacing each non-zero entry in a row of the first parity check matrix with a non-zero column of a Cordaro-Wagner component code check matrix, wherein:

- a row having exactly three non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix, where the columns of the Cordaro-Wagner component code check matrix which correspond to the $2k$ parity check matrix columns are linearly independent; and
- a row having exactly four non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix, where the columns Cordaro-Wagner component code check matrix which correspond to the $2k$ parity check matrix columns comprise three linearly independent columns.

The fifth to the eighth possible implementation forms facilitate achieving a repeat-accumulate code structure.

As noted above, the determined GLDPC code may be used for forward error correction in the system 10 of Fig. 1.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a block diagram illustrating a generic digital communications system in which the elements of the present disclosure may be implemented.

Fig. 2 is a flow-chart of a procedure for determining the GLDPC code.

5 Fig. 3 illustrates an exemplary structure of the parity part of the first parity check matrix.

Fig. 4 illustrates an exemplary structure of the parity part of the second parity check matrix.

Fig. 5 shows additional steps of the procedure illustrated in Fig. 2.

DETAILED DESCRIPTION

The following provides a non-limiting example of a procedure for determining a GLDPC code
 10 for forward error correction. The procedure as well as procedures involving the usage of the determined GLDPC code may be implemented by hardware, software, or a combination of hardware and software. For example, the procedure of determining the GLDPC code may be automatically carried-out by a computer comprising a processor which carries out machine-readable instructions persistently stored on a machine-readable medium. Moreover, procedures
 15 involving the usage of the determined GLDP code, such as encoding/decoding an information sequence IS_i may be automatically carried-out by the system 10 which may have been designed or configured in accordance with the determined GLDPC code.

As shown in Fig. 2, the procedure may involve a step 22 of determining $2k$ parity check matrix columns of size k as shown in Fig. 3 which illustrates an exemplary structure of a parity part
 20 28 of the first parity check matrix 30 in array form, wherein black squares indicate entries of non-zero weight (i.e., '1s') and white squares indicate entries of zero weight (i.e., '0s'). The parity part 28 comprises the determined ten columns of length five. In the exemplary structure, the columns of the parity part are linearly independent and comprise either one or two entries of non-zero weight. In particular, four columns have one entry of non-zero weight and the

remaining columns have two entries of non-zero weight.

At step 24, the procedure may be continued with labelling components of the first parity check matrix 30 with n columns and k rows, wherein the first parity check matrix 30 includes the $2k$ parity check matrix columns of size k . As shown in Fig. 3, labelling the components may involve labelling the columns of the information part 32 of the first parity check matrix 30. For example, as indicated in step 34 in Fig. 5, the information part 32 may be labelled by performing a progressive edge growth algorithm.

At step 26, Cordaro-Wagner component code check matrices may be selected, wherein each of the selected Cordaro-Wagner component code check matrices has two rows which replace a row of the first parity check matrix to derive a second parity check matrix defining the generalized LDPC code. For example, as indicated in step 36 of Fig. 5, each entry of the parity part 28 may be split/duplicated into a vector of size two, wherein entries of zero weight are split/duplicated into a zero vector whereas entries of non-zero weight are split/duplicated into a vector having one or two non-zero entries.

As shown in in Fig. 4, the replacing may be made under the provision that the rows and columns of the parity part 28' consisting of $2k$ columns of the second parity check matrix can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure. For example, the parity part H_2 of the LDPC parity-check matrix:

$$H_2^{EIRA} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 \end{bmatrix}$$

may be chosen such that, after replacing the rows of the first parity check matrix with rows of a Cordaro-Wagner component code, an extended irregular repeat-accumulate (EIRA) code can be obtained.

Replacing may start at the first row of H_2^{EIRA} which has the following entries:

$$1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1$$

By replacing the entries with vectors of size two using $\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}$, two rows of a generalized EIRA (GEIRA) code may be maintained, wherein the rows have the entries

5

$$\begin{array}{cccccccccc} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \end{array}$$

The second row of the parity part H_2^{EIRA} which has

$$1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0$$

as entries may be replaced using $\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ with another two rows of the GEIRA code having

10

$$\begin{array}{cccccccccc} 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}$$

as entries. The third row of the parity part H_2^{EIRA} which has

$$0 \ 1 \ 0 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 1$$

as entries may be replaced using $\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ with another two rows of the GEIRA code having

$$\begin{array}{cccccccccc} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \end{array}$$

as entries. The fourth row of the parity part H_2^{EIRA} which has

$$0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1 \ 0 \ 0 \ 0$$

as entries may be replaced using $\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ with another two rows of the GEIRA code

5 having

$$\begin{array}{cccccccccc} 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \end{array}$$

as entries. The fifth row of the parity part H_2^{EIRA} which has

$$0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1 \ 0$$

as entries may be replaced using $\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ with another two rows of the GEIRA code

10 having

$$\begin{array}{cccccccccc} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \end{array}$$

as entries. The parity part of the second parity check matrix may thus be

$$H_2^{GEIRA} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \end{bmatrix}$$

After reordering the columns in accordance with

$$P_{column} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ 1 & 3 & 2 & 5 & 4 & 7 & 6 & 9 & 8 & 10 \end{pmatrix}$$

and reordering the rows in accordance with

$$P_{row} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ 1 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 2 \end{pmatrix}$$

an EIRA structure may be obtained:

$$H_2^{EIRA} = \begin{matrix} & 1 & 3 & 2 & 5 & 4 & 7 & 6 & 9 & 8 & 10 \\ \begin{matrix} 1 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \\ 9 \\ 10 \\ 2 \end{matrix} & \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \end{bmatrix} \end{matrix}$$

In this regard, it is noted that although the procedure is described in relation to a specific example of size 5×10 , codes of other sizes may be generated analogously:

$$H_2^{GEIRA} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 1 & \cdots & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & \cdots & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cdots & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & \cdots & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 \end{bmatrix}$$

Heretofore:

- 5 a. non-zero entries in a row of the parity part with three non-zero entries may be replaced by $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$, $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$, and $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$, respectively.
- b. non-zero entries in a row of the parity part with four non-zero entries may be replaced by $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$, $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$, $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$, and $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$, respectively.
- c. columns and rows may be reordered in accordance with

$$10 \quad P_{column} = \begin{pmatrix} 1 & 2 & 3 & \cdots & 2s & 2s+1 & \cdots & k & k \\ 1 & 3 & 2 & \cdots & 2s+1 & 2s & \cdots & a & k \end{pmatrix},$$

$$\text{with } a = \begin{cases} k, k \text{ is even} \\ k-1, k \text{ is odd} \end{cases}, s = 2 \dots \overline{\left\lfloor \frac{k}{2} \right\rfloor}, \text{ and}$$

$$P_{row} = \begin{pmatrix} 1 & 2 & 3 & \cdots & s & \cdots & k \\ 1 & 3 & 4 & \cdots & s+1 & \cdots & 2 \end{pmatrix},$$

$$\text{with } s = \overline{2 \dots k-1}.$$

Once, the EIRA structure has been obtained, encoding may be performed as described in US 7,627,801 B2 or in EP 1,816,750 A1.

Moreover, decoding may be performed as described in EP 1,816,750 A1.

CLAIMS

1. A system for determining a generalized LDPC code for forward error correction channel coding, the system being configured to:

determine $2k$ parity check matrix columns of size k ;

5 label components of a first parity check matrix with n columns and k rows, wherein the first parity check matrix includes the $2k$ parity check matrix columns of size k ; and

select Cordaro-Wagner component code check matrices, wherein each of the selected Cordaro-Wagner component code check matrices has two rows which replace one row of the first parity check matrix to derive a second parity check matrix defining the generalized LDPC code;

10 wherein the determining of the $2k$ parity check matrix columns of size k and the selecting of the Cordaro-Wagner component code check matrices are constrained to $2k$ parity check matrix columns of size k and Cordaro-Wagner component code check matrices which allow that rows and columns of a parity part consisting of $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k , can be brought in an order in which
15 the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

2. The system of claim 2, the system being configured to:

split/duplicate each entry of the $2k$ parity check matrix columns of size k into a vector of size two, wherein each vector of size two having a non-zero weight requires a corresponding non-zero entry, to determine the $2k$ columns of the second parity check matrix which correspond to
20 the $2k$ parity check matrix columns of size k , and can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

3. The system of claim 1 or 2, the system being configured to:

iteratively label components of $n-k$ unlabeled columns of the first parity check matrix based on a performance measure.

5 4. The system of any one of claims 1 to 3, the system being configured to:

compare multiple alternatives for labelling different components of the $n-k$ columns with non-zero entries; and

select one alternative achieving a highest performance score.

10 5. The system of any one of claims 1 to 4, wherein a column of the Cordaro-Wagner component code check matrix is to have zero weight if a corresponding component of the row of the first parity check matrix is zero.

15 6. The system of any one of claims 1 to 5, wherein each of the $2k$ parity check matrix columns of size k has weight one or two.

7. The system of claim 6, wherein $k-1$ parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have a weight of one and the remaining parity check matrix columns of size k of the $2k$ parity check matrix columns of size k have weight two.

8. The system of any one of claims 1 to 7, wherein the $2k$ parity check matrix columns of size k are linearly independent.

5 9. The system of any one of claims 1 to 8, wherein selecting the Cordaro-Wagner component code check matrices includes replacing each non-zero entry in a row of the first parity check matrix with a non-zero column of a Cordaro-Wagner component code check matrix, wherein:

10 a row having exactly three non-zero entries in components which correspond to the $2k$ parity check matrix columns, is replaced with a Cordaro-Wagner component code check matrix having columns which correspond to the $2k$ parity check matrix columns, wherein said columns are linearly independent; and

15 a row having exactly four non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix having columns which correspond to the $2k$ parity check matrix columns, wherein three of said columns are linearly independent.

10. A method of determining a generalized LDPC code for forward error correction channel coding, the method comprising:

20 determining $2k$ parity check matrix columns of size k ;

labeling components of a first parity check matrix with n columns and k rows, wherein the first parity check matrix includes the $2k$ parity check matrix columns of size k ; and

selecting Cordaro-Wagner component code check matrices, wherein each of the selected Cordaro-Wagner component code check matrices has two rows which replace a row of the first parity check matrix to derive a second parity check matrix defining the generalized LDPC code;

wherein the determining of the $2k$ parity check matrix columns of size k and the selecting of the Cordaro-Wagner component code check matrices are constrained to $2k$ parity check matrix columns of size k and Cordaro-Wagner component code check matrices which allow that rows and columns of a parity part consisting of $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

10

11. The method of claim 10, the method comprising:

splitting/duplicating each entry of the $2k$ parity check matrix columns of size k into a vector of size two, wherein each vector of size two having a non-zero weight requires a corresponding non-zero entry, to determine the $2k$ columns of the second parity check matrix which correspond to the $2k$ parity check matrix columns of size k , and can be brought in an order in which the ordered rows and columns form a parity part which has a repeat-accumulate code structure.

15

12. The method of claim 10 or 11, comprising:

iteratively labeling components of $n-k$ unlabeled columns of the first parity check matrix based on a performance measure.

20

13. The method of any one of claims 10 to 12, comprising:

comparing multiple alternatives for labelling different components of the $n-k$ columns with non-zero entries; and

selecting one alternative achieving a highest performance score.

- 5 14. The method of any one of claims 10 to 13, wherein a column of the Cordaro-Wagner component code check matrix has zero weight if a corresponding component of the row of the first parity check matrix is zero and/or

each of the $2k$ parity check matrix columns of size k has weight one or two; and/or

the $2k$ parity check matrix columns of size k are linearly independent.

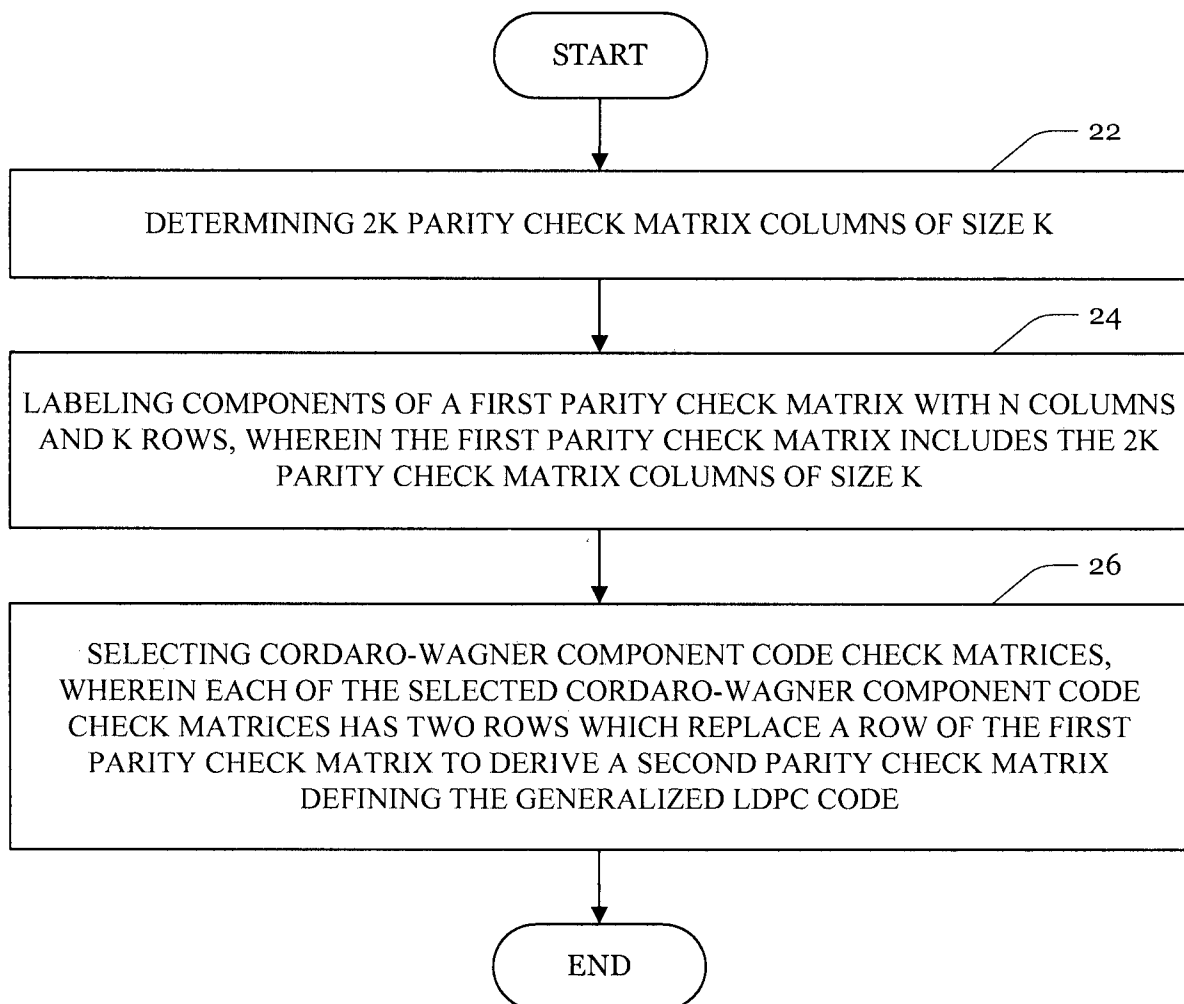

10

15. The method of any one of claims 10 to 14, wherein selecting the Cordaro-Wagner component code check matrices includes replacing each non-zero entry in a row of the first parity check matrix with a non-zero column of a Cordaro-Wagner component code check matrix, wherein:

- 15 a row having exactly three non-zero entries in components which correspond to the $2k$ parity check matrix columns, is replaced with a Cordaro-Wagner component code check matrix having columns which correspond to the $2k$ parity check matrix columns, wherein said columns are linearly independent; and

- 20 a row having exactly four non-zero entries in components which correspond to the $2k$ parity check matrix columns is replaced with a Cordaro-Wagner component code check matrix having columns which correspond to the $2k$ parity check matrix columns, wherein three of said columns are linearly independent.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/RU2017/000522

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 10-15
because they relate to subject matter not required to be searched by this Authority, namely:
see FURTHER INFORMATION sheet PCT/ISA/210
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- ☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- ☐ No protest accompanied the payment of additional search fees.

Continuation of Box II.1

Claims Nos.: 10-15

Rule 39.1(i) PCT - Mathematical method

The subject-matter of claims 10-15 does not have a technical character but said claims solely comprise purely mathematical method steps. In particular, independent claim 10 specifies a method for determining a generalized LDPC code for forward error correction channel coding comprising solely mathematical method steps related to the construction of a parity check matrix representing the generalized LDPC code. It is noted that a generalized LDPC code which is composed of codewords with length n is a subset of all binary vectors of length n . Consequently, generalized LDPC codes as such are purely mathematical constructions which have no technical character and this also applies to the construction of their representing parity check matrix. It is further noted that a method for determining a generalized LDPC code for forward error correction channel coding only fulfils the requirements of Rule 39 PCT if technical means for carrying out the method are claimed (see claims 1-9) or if an additional method step of using the constructed parity check matrix of the generalized LDPC code in an encoding scheme for forward error correction channel coding is claimed.
